In this research, we investigated implicit learning in schizophrenia by measuring the effects of a disruptive stimulus on the accuracy of learning. Participants were 16 medication-naïve, acutely ill individuals diagnosed with schizophrenia and 16 age- and education-matched controls. Participants performed an auditory task that they had completed on previous occasions, consisting of a sequence of tones, as well as a condition in which the tones were preceded by a visual cue, without any task demands. Participants were trained on the sequence task on two separate sessions, with a gap between sessions. Between the sessions, the delay between the tones in the sequence was either 100 ms (n = 10) or 200 ms (n = 6). Consistent with previous findings, controls showed implicit learning in the 100-ms delay condition. Individuals with schizophrenia had no implicit learning in the 100-ms delay condition and showed a response bias towards the end of the sequence, which was unaffected by the delay condition. In contrast, controls had implicit learning in the 200-ms delay condition. Individuals with schizophrenia had implicit learning in the 200-ms delay condition, which was unaffected by the delay condition. However, the magnitude of implicit learning in this group was markedly reduced relative to controls. In both groups, implicit learning was facilitated in the 200-ms delay condition relative to the 100-ms delay condition. The findings suggest that individuals with schizophrenia are not able to effectively integrate contextual information in order to acquire associations. This abstract was presented in the following presentation form: Ketler, J., Mestre, C., Brodtkin, K. S., Sesia, P. F. M., & Linszen, D. (2007).
